EDUCATION

Master of Informatics, Kyoto University, Graduate School of Informatics 2026.4 – Expected 2028.3

Bachelor of Engineering, Kansai University, Department of Civil, Environmental and Applied Systems Engineering 2021.4 – 2026.3

SKILLS

Completed Course. Data Structures and Algorithms, Operating Systems, Introduction to Artificial Intelligence, Computer Networks, Information Security, Information Theory, Database Systems and so on

Programming Skills. Python, Golang, C, Vimscript, SQL, Rust

Tools and Frameworks. Node.js, Git, Linux, PyTorch, Docker, Vim, PostgreSQL, k8s

Language Skills. English (TOEIC score: 880/990), Japanese (JLPT N1), Chinese (Native)

PROJECTS

Mogu Mogu. In this project, I was responsible for backend development and system architecture design for an AI-powered calendar application that recommends daily meals based on users' recent schedules, activities, and dietary records. I designed and implemented core API flows, JWT-based authentication, user profile and preference management, calendar event management, meal history tracking, and dietary preference modeling. The recommendation workflow analyzes upcoming events, recent activity intensity, and past eating patterns, then assembles structured prompts to generate personalized daily nutrition suggestions. I also designed middleware controls for request validation, authorization, and session handling to support secure and reliable API access. The primary technology stack of this project includes Go, Gin, GORM, PostgreSQL, and JWT.

Simblock_go. In this project, I was responsible for designing and developing simblock_go, a high-performance Go reimplement of SimBlock, a blockchain network simulator originally developed by my affiliated group(Data Engineering and Platform Research Group). The goal is to migrate and optimize the platform to simulate block propagation and consensus dynamics with superior execution efficiency. The main features include a discrete-event simulation engine, network topology processing, Proof-of-Work (PoW) consensus, and an asynchronous message task dispatching system (handling Inv, Block, and CmpctBlock messages). Node routing and multi-region propagation are fully implemented through event timers and custom task queues. The primary technology stack includes Go, YAML configuration, shell script, and an integration testing framework.

Conference Paper. In this paper, I proposed and implemented GOFA, a gradient-oriented backdoor attack method for exposing security vulnerabilities in Vertical Federated Learning (VFL) systems. The main contribution is constructing poisoned training datasets without prior knowledge by leveraging gradients returned from the server. I also used gradient-based adversarial example attacks to mask the original features of poisoned samples, thereby forcing the model to rely more heavily on the injected trigger. The approach was evaluated on datasets including CIFAR-10 and UCI-HAR using Python, PyTorch, TorchVision, and CUDA acceleration. This work has been peer-reviewed and accepted by the 6th International Conference on Electrical, Computer and Energy Technologies (ICECET2026).

EXTRACURRICULAR ACTIVITIES

- **2022–2023 Kura Sushi.**

During my time at Kura Sushi, I worked as a part-time kitchen staff member where I was primarily responsible for preparing sushi and making tempura.
